FOREST INSECT CONDITIONS

IN THE PACIFIC NORTHWEST

1967

INSECT AND DISEASE CONTROL BRANCH
DIVISION OF TIMBER MANAGEMENT
PACIFIC NORTHWEST REGION
U. S. DEPARTMENT OF AGRICULTURE
FOREST SERVICE

MARCH 1968

This is the 20th annual report
of forest insect conditions in Oregon
and Washington based on cooperative surveys
sponsored by the Northwest Forest Pest Action Council.
The combined efforts of many organizations and individuals
made these surveys possible. Special acknowledgement
is made to the principal cooperators: Oregon
State Board of Forestry and Washington
Department of Natural Resources.

COVER BACKGROUND: Egg and larval galleries of *Orthotomicus ornatus* Sw. on the bark of ponderosa pine.

FOREST INSECT CONDITIONS IN THE PACIFIC NORTHWEST

DURING 1967

BY

R. E. DOLPH

AND

L. F. PETTINGER

FEBRUARY 1968

INSECT AND DISEASE CONTROL BRANCH
DIVISION OF TIMBER MANAGEMENT
PACIFIC NORTHWEST REGION
U. S. FOREST SERVICE

SURVEY FINDINGS IN BRIEF

Forest insect outbreaks were reported on 1,910,900 acres in Oregon and Washington in 1967 (table 1). Defoliators accounted for 55 percent of this damage, bark beetles contributed 36 percent, and 9 percent was attributed to sucking insects. During the last decade, the trend of infestations was as follows.

Year	Infested acreage	Year	Infested acreage
1958	2,032,720	1963	1,311,085
1959	1,448,360	1964	1,116,130
1960	1,272,960	1965	1,402,610
1961	1,223,230	1966	1,220,712
1962	1,305,170	1967	1,910,900

The extent and intensity of outbreaks by insect species occurring in Oregon are given in table 41 and in Washington in table 42. The major problem areas of insect outbreaks are shown in the generalized map in figure 2.

Both States are divided into forest insect reporting areas as shown on the inside of back cover. These insect reporting areas are a simple convenience for reporting conditions in a geographical area. No attempt has been made to summarize insect outbreaks according to land ownership within an individual reporting area.

The main findings of aerial and ground surveys in 1967 were:

1. Mountain pine beetle.--Outbreaks in western white pine stands increased in both Oregon and Washington. Outbreaks on ponderosa pine were static in Washington and decreased in Oregon, but the potential for catastrophic outbreaks still remains. Tree killing in lodgepole pine stands increased greatly. Outbreaks on sugar pine remained at a low level.

2. Douglas-fir beetle.--The destructive outbreaks increased in Washington. Losses decreased in eastern Oregon, and remained static in western Oregon.

3. Western pine beetle.--Losses were higher in Oregon and lower in Washington. Subepidemic tree killing increased in many ponderosa pine stands, indicating a possible beetle population build-up.

4. Fir engraver.--Tree killing increased in Oregon and Washington.

5. Oregon pine ips.--The size and intensity of the infestations increased. Epidemic damage was sustained in many ponderosa pine sapling stands.

6. Engelmann spruce beetle.--Losses were generally downward, with some localized damage increasing.

7. Silver fir beetles.--Losses decreased in Pacific silver fir stands of Washington. No epidemic losses were reported in Oregon.

8. Larch casebearer.--Infestations of this introduced insect continued to spread in the western larch stands of eastern Washington. Parasites were released for the second year.

9. Larch sawfly.--Outbreaks decreased in Oregon and increased in Washington.

10. Larch bud moth.--Widespread epidemic outbreaks occurred in northeastern Washington.

11. Pine needle miner.--Outbreaks decreased in the ponderosa and lodgepole pine stands of central Oregon.

12. Western hemlock looper.--A comparatively small area of very heavy defoliation occurred on the Mt. Baker National Forest in Washington.

13. European pine shoot moth.--The infestation continued to spread within the Containment Zone in western Washington. Numerous infested pines were detected in several communities in southeastern Washington and northeastern Oregon. All infested pines found in Portland, Oregon, were fumigated or destroyed to eradicate the insect.

14. Black-headed budworm.--Subepidemic populations exist at several locations in both States.

15. Balsam woolly aphid.--Damage increased in both States. Infestations were found further south in the southern Coast Range of Oregon.

Table 1.--Summary of 1967 forest insect epidemic infestations in Oregon and Washington

Insects [1]	Oregon		Washington		Regional total	
	Infestation centers	Area	Infestation centers	Area	Infestation centers	Area
	Number	Acres	Number	Acres	Number	Acres
Defoliators:						
Sawflies on true firs	3	4,400	0	0	3	4,400
Sawflies on larch	2	680	16	15,660	18	16,340

Larch bud moth	0	0	76	139,060	76	139,060
Western hemlock looper	0	0	1	1,600	1	1,600
Needle miners (L)	34	80,460	0	0	34	80,460
Needle miners (P)	5	4,800	0	0	5	4,800
Larch casebearer	0	0	121	783,650	121	783,650
Forest tent caterpillar on red alder	8	10,990	0	0	8	10,990
All defoliators	68	107,850	214	939,970	282	1,047,820
Sucking insects:						
Balsam woolly aphid	466	116,080	97	41,470	563	157,550
Spider mites	12	13,200	0	0	12	13,200
All sucking insects	478	129,280	97	41,470	575	170,750
Bark beetles:						
Douglas-fir beetle (Westside)	643	47,710	69	15,960	712	63,670
Douglas-fir beetle (Eastside)	61	2,480	247	37,450	308	39,930
Douglas-fir engraver	3	220	0	0	3	220
Engelmann spruce beetle	22	3,170	24	4,650	46	7,820
Fir engraver	298	25,470	46	3,580	344	29,050
Mountain pine beetle (L)	354	186,690	8	2,530	362	189,220
Mountain pine beetle (S)	13	1,000	0	0	13	1,000
Mountain pine beetle (W)	428	90,040	240	74,280	668	164,320
Mountain pine beetle (P)	275	43,090	102	18,290	377	61,380
Oregon pine ips	633	55,170	11	900	644	56,070
Western pine beetle	418	65,870	26	6,730	444	72,600
Silver fir beetles	0	0	30	7,050	30	7,050
All bark beetles	3,148	520,910	803	171,420	3,951	692,330
All insects	3,694	758,040	1,114	1,152,860	4,808	1,910,900

1/ Mountain pine beetle and needle miner infestations are separated by tree species: L, lodgepole pine; S, sugar pine; W, western white pine; P, ponderosa pine.

INTRODUCTION

Epidemic outbreaks of forest insects were detected and mapped according to intensity of damage from the air. Ground surveys were made to verify the aerial survey findings, detect sub-epidemic insect populations, and evaluate threat and insect population trends.

The problems of bear damage to forest trees and dying hemlock were recorded and discussed at the request of the Northwest Forest Pest Action Council.

MAJOR DEFOLIATOR PROBLEMS

Standards used in the aerial detection survey for evaluation of forest defoliator outbreaks are as follows:

Defoliation intensity	Appearance of damage
Light	Barely visible from air
Moderate	Top 1/4 of tree defoliated
Heavy	Top 1/2 of tree defoliated
Very heavy	Top 3/4 of tree defoliated

LARCH CASEBEARER, *Coleophora laricella* (Hübner)

Host: Western larch.

Damage: Infestations continued to spread in northeast Washington where light to extremely heavy populations of the moth can now be found in over 8,000 square miles of larch forests. This year the insect was found west of the Okanogan River at Loup Loup Summit on the Okanogan National Forest and was found for the first time in southeast Washington in Garfield and Asotin Counties (figure 1).

Over 783,000 acres of visible damage was mapped by aerial survey contrasted to approximately 470,000 acres in 1966 (table 2). Defoliation varies from light to extreme. Tree growth has been reduced in older infestation centers, but as yet no tree mortality has occurred.

The majority of the damage recorded occurred on the Colville and Kaniksu National Forests and the Northeast Washington District (table 3).

Distribution of larch casebearer in northeastern Washington.
1964 Infestation boundary
1965 " "
1966 " "
1967 " "
1966 Parasite liberation plots
1967 " " "
Scale: 0 10 20 30 40 Miles.

Trend: The insect is expected to continue its spread throughout the larch stands of eastern Washington and can be expected to move into northeastern Oregon within the next few years. Parasite liberations are not expected to cause any reduction in defoliation for 5 to 10 years.

Control: Parasites were liberated at 11 localities in 1966 and 8 locations in 1967. More liberations are planned for 1968.

Table 2.--Trend of larch casebearer infestations in Washington, 1963-67

LARCH SAWFLY, *Pristiphora erichsonii* (Htg.)

Host: Western larch.

Damage: Infestations of the larch sawfly continued in Oregon and Washington. Damage increased in northeast Washington with most of the losses located on the Okanogan and Colville National Forests (table 4).

In Oregon the infestation on the Warm Springs Indian Reservation subsided, but new and smaller infestations developed on the Mt. Hood National Forest.

Trend: Upward in Washington and static in Oregon. Tree mortality has not occurred from the defoliation, nor is any expected in the immediate future.

Control: Control is not needed in 1968. Parasites and predators usually reduce most sawfly populations within a year or two.

Table 4.--Extent of larch sawfly infestations in Oregon and Washington in 1967, by reporting area and intensity of infestation

LARCH BUD MOTH, *Zieraphera griseana* (Hbn.)

Host: Western larch.

Damage: This moth caused widespread defoliation in north central Washington where light to heavy damage occurred at several localities. All damage was located on the Colville and Okanogan National Forests and the Colville Indian Reservation (table 5).

Trend: Undetermined, probably downward.

Control: Control will not be needed in 1968. The outbreak is expected to be short lived.

Table 5.--Extent of larch budmoth infestations in Washington in 1967, by reporting area and intensity of infestation

1/ N.F., National Forest; I.R., Indian Reservation

EUROPEAN PINE SHOOT MOTH, *Rhyacionia buoliana* (Schiff.)

Hosts: Mugho, lodgepole, and Scotch pines are preferred hosts, but all species of pines are subject to attack.

Damage: Ornamental pines in 83 communities and growing stock in 44 Christmas tree plantations were surveyed outside the Containment Zone in Washington. Infested trees were found in Longview, Tenino, College Place, Prosser, Kennewick, and Walla Walla. The moth continued to spread and tree damage intensified in the Containment Zone.

In Oregon infested trees were found west of the Cascade Mountains at two locations in Portland. Well-established infestations were detected at Hermiston, Umatilla, and at McNary Dam east of the Cascade Mountains in Oregon. All infested trees in the Portland metropolitan area were fumigated or destroyed before moth flight. All other infestations outside the Containment Zone are being evaluated before control action is recommended.

Trend: Continued spread of the infestation through movement of infested stock can be expected.

Control: We have procedures and schedules for fumigating pine in bundles, as container stock, or as liners in place. This fumigating, together with strict enforcement of existing quarantines, will slow the spread of the moth.

NEEDLE MINER, *Coleotechnites* near *milleri*

Hosts: Lodgepole and ponderosa pines.

Damage: Continued attacks occurred on lodgepole and ponderosa pine in the upper Deschutes Basin on the Deschutes and Winema National Forests (tables 6 and 7). Infestations increased in intensity and caused some tree mortality in the older infestations.

Trend: Moderate to heavy defoliation and increased tree killing is expected next year.

Control: No control is needed in 1968.

Table 6.--Extent of needle miner infestations on lodgepole pine in Oregon in 1967, by reporting area and intensity of infestation

1/ N.F., National Forest

WESTERN HEMLOCK LOOPER, *Lambdina fiscellaria lugubrosa* Hulst

Host: Western hemlock

Damage: Very heavy defoliation occurred on 1,600 acres in the Bacon Creek drainage on the Mt. Baker National Forest in Washington. Fall egg surveys indicate the infestation is spreading in Bacon Creek and building up at several widely scattered locations on the Forest. Defoliation is expected next year in the Cascade River, Finney Creek, and Whitehorse Mountain area. Tree mortality is expected in the heavily defoliated area in Bacon Creek. Larval collections from ground detection plots along the coastal region of Oregon and Washington showed no significant population buildups.

Trend: Upward.

Control: Plans call for field testing promising insecticides to find a substitute for DDT, should control of a large looper infestation become necessary.

MAJOR SUCKING INSECT PROBLEMS

BALSAM WOOLLY APHID, *Adelges piceae* (Ratz.)

Hosts: Pacific silver fir, subalpine fir, and grand fir.

Damage: The infested acreage nearly tripled that reported in 1966 (table 8). The majority of the damage occurred in the Cascades with lesser amounts in the Coast Range. Seventy-four percent of the Regional losses were reported in Oregon with most of the damage located on the Mt. Hood, Umpqua, and Willamette National Forests.

In Washington, most of the losses occurred on the Gifford Pinchot and Snoqualmie National Forests (table 9).

Trend: A slight increase is expected next year in the Cascade Mountains of both States.

Control: No practical control method is available for use under forest conditions in commercial stands. Logging of infested, merchantable trees and those of declining thrift is the only means of combating this pest.

Limited field tests of promising insecticides are being made against the aphid on recreational sites in the vicinity of Mt. St. Helens. Several subalpine fir were sprayed with a back-pack mist blower using Baygon, a carbamate insecticide. Additional tests are planned for 1968.

MITES

Hosts: True firs and Douglas-fir.

Damage: The spider mite infestations reported last year on the Malheur National Forest, Oregon have declined considerably. Very light defoliation occurred on 350 acres of Douglas-fir and true fir.

A larger spider mite infestation was detected near Hebo Mountain on the Siuslaw National Forest in Oregon. Moderate to heavy defoliation of the current year's foliage occurred on 12,850 acres of a 56-year-old Douglas-fir plantation.

A small outbreak of an eriophyid mite, *Trisetacus pseudotsugae* K., occurred on the Tillamook Forest of the Northwest Oregon State District. This mite caused light damage to the tops of young Douglas-fir. Similar damage was observed on western hemlock and true firs.

Trend: Unknown, probably downward.

Control: Direct control is not needed as insect predators usually keep mite populations in check.

MAJOR BARK BEETLE PROBLEMS

MOUNTAIN PINE BEETLE, *Dendroctonus ponderosae* Hopk.

Mountain pine beetle damage accounted for 60 percent of the losses attributed to bark beetles. About 85 percent of the mountain pine beetle losses occurred in lodgepole pine and western white pine stands. The remaining losses were located in young ponderosa pine and in old-growth sugar pine stands. The damage is discussed below by major host.

Host: Lodgepole pine.

Damage: Losses nearly doubled the total reported in 1966 (table 10). Region-wide, 99 percent of the tree killing occurred in Oregon with 89 percent of the losses located on the Deschutes, Fremont, and Winema National Forests. Significant tree killing was found on the Colville, Okanogan, and Wenatchee National Forests in Washington (table 11).

Trend: Tree killing is expected to remain high in the overmature stands in both States.

Control: Logging merchantable infested and intermingled green trees is recommended to reduce beetle populations and salvage timber values.

Host: Western white pine.

Damage: Fifty-five percent of the losses occurred in Oregon (table 12). Tree killing on the Willamette National Forest accounted for 78 percent of the losses detected in Oregon. Significant losses were also reported on the Mt. Hood and Umpqua National Forests.

Tree killing in Washington remained static. Most of the losses, 62 percent of the State total, occurred on the Quinault Indian Reservation and the Wenatchee and Snoqualmie National Forests (table 13).

Trend: The damage is expected to remain static in Washington due to the depletion of susceptible host; however, mortality in Oregon will continue at its present high rate.

Control: Logging merchantable infested and intermingled green trees is recommended to reduce beetle populations and salvage timber values. Direct control is impractical in western white pine due to the prevalence of blister rust.

Host: Ponderosa pine.

Damage: Region-wide, the infested acreage had increased (table 14). Seventy percent of the losses occurred in Oregon with over 50 percent of the mortality located on the Wallowa-Whitman National Forest. In Washington, most of the losses were found on the Okanogan National Forest (table 15).

Results of a recent survey on the Wallowa-Whitman National Forest in a 10-year-old mountain pine beetle infestation show growth has been set back for about 30 years. Stocking, basal area, and the average tree diameter in the stand has been greatly reduced.

Trend: Ponderosa pine losses are expected to remain high in local areas in both States.

Control: Thinning of dense, overstocked stands before the beetles attack is encouraged. Direct control is used in pole-size stands only as a "stop-gap" measure to reduce the beetle population.

Host: Sugar pine.

Damage: The number of infested acres in Oregon decreased from the high recorded in 1963 (table 16). Most of the tree killing occurred on the Rogue River and Umpqua National Forests (table 17).

Trend: Losses are expected to be less in 1968.

Control: Logging merchantable infested and intermingled green trees is recommended to reduce populations and salvage timber values.

1/ N.F., National Forest

DOUGLAS-FIR BEETLE, *Dendroctonus pseudotsugae* Hopk.

Host: Douglas-fir.

Damage: Douglas-fir beetle damage increased in Oregon and Washington west of the Cascade Mountains (table 18). In Oregon, 75 percent of the losses occurred on the Illinois Valley District, Siskiyou National Forest, and on the Applegate District, Rogue River National Forest. In western Washington, most of the mortality was detected on the Gifford Pinchot National Forest (table 19).

Tree killing east of the Cascade Mountains increased in Washington and decreased in Oregon (table 20). Ninety-four percent of the losses occurred in Washington with 69 percent of this damage located on the Okanogan and Colville National Forests (table 21). Significant killing was also detected on the Colville Indian Reservation. In Oregon, most of the damage occurred on the Wallowa-Whitman National Forest.

Trend: A downward trend is expected in the westside Douglas-fir stands and an upward trend in the eastside Douglas-fir stands.

The present increase of losses on the Rogue River and Siskiyou National Forests is the result of the 1964-65 floods. These floods weakened many trees along stream banks, caused earth slides, and provided many breeding sites for the beetles.

Control: Continued salvage of infested trees and recently windthrown trees will help reduce beetle populations and save timber values that would otherwise be lost.

OREGON PINE IPS, *Ips pini* Say

Host: Ponderosa pine.

Damage: The total infested acreage increased 12 times over the loss recorded in 1966 (table 22). Most of the damage occurred in second-growth ponderosa pine stands. Infestations in Oregon accounted for 98 percent of the Regional losses with 56 percent of the damage located on the Wallowa-Whitman National Forest. Tree killing in Washington was detected on four different Forests, but losses never exceeded 400 acres on any one of the Forests (table 23).

Trend: Indications are that ips losses will be higher next year. Some of this loss will be due to the 1967 drought and the abundance of scorched trees around recent fires.

Control: Because outbreaks develop and subside rapidly, control is generally not recommended.

WESTERN PINE BEETLE, *Dendroctonus brevicomis* Lec.

Host: Ponderosa pine.

Damage: Western pine beetle epidemics increased in many areas of eastern Oregon and decreased in eastern Washington. Scattered tree killing was observed throughout most pine stands in both States. In Oregon, 54 percent of the State's losses occurred on three National Forests--Fremont, Malheur, and Ochoco (table 24). Significant damage was also reported on the Warm Springs Indian Reservation and the Rogue River National Forest. The most extensive tree killing in Washington occurred on the Yakima Indian Reservation (table 25).

Trend: Static to upward in both States.

Control: Increased sanitation-salvage programs in overmature ponderosa pine stands should hold tree killing to a minimum. Logging infested trees aids in reducing beetle populations.

1/ N.F., National Forest; I.R., Indian Reservation; N.P., National Park

FIR ENGRAVER, *Scolytus ventralis* Lec.

Hosts: Grand fir, subalpine fir, and white fir.

Damage: Infestations in Oregon accounted for 88 percent of the losses in the Northwest (table 26). In Oregon, 66 percent of the outbreaks were found on the Wallowa-Whitman and Umatilla National Forests. Losses in Washington remained static with most of the tree killing occurring on the Okanogan National Forest (table 27).

Trend: Probably upward. Beetle activities increase during drought periods. The 1967 drought in Oregon, the longest on record, is expected to favor an increase in damage caused by the fir engraver.

Control: Control, other than logging merchantable, infested trees, is seldom necessary because fir engravers usually subside when moisture conditions return to normal. Spotting infested trees is difficult since broods frequently develop and emerge without killing the trees.

SILVER FIR BEETLES, *Pseudohylesinus* spp.

Host: Pacific silver fir.

Damage: Outbreaks of these beetles subsided (table 28). Epidemic outbreaks occurred on several areas of the Mt. Baker and Snoqualmie National Forests in Washington (table 29). Many of the infested areas are also heavily infected with *Armillaria mellea* root rot. For the fifth consecutive year, no outbreaks were reported in Oregon.

Trend: Presumably downward.

Control: No control other than logging infested trees and those of declining thrift in outbreak centers is needed in 1968.

ENGELMANN SPRUCE BEETLE, *Dendroctonus obesus* (Mann.)

Host: Engelmann spruce.

Damage: Infestations remained static in Washington with most of the tree killing centered on the Okanogan National Forest (table 30). In Oregon, all of the losses occurred on the Wallowa-Whitman and Umatilla National Forests (table 31). Most of the infested acreage in both States is found at high elevations and in inaccessible areas.

Trend: Static in both Washington and Oregon.

Control: None is needed. In accessible stands, infested merchantable trees should be salvaged to reduce beetle populations.

CONE AND SEED INSECTS

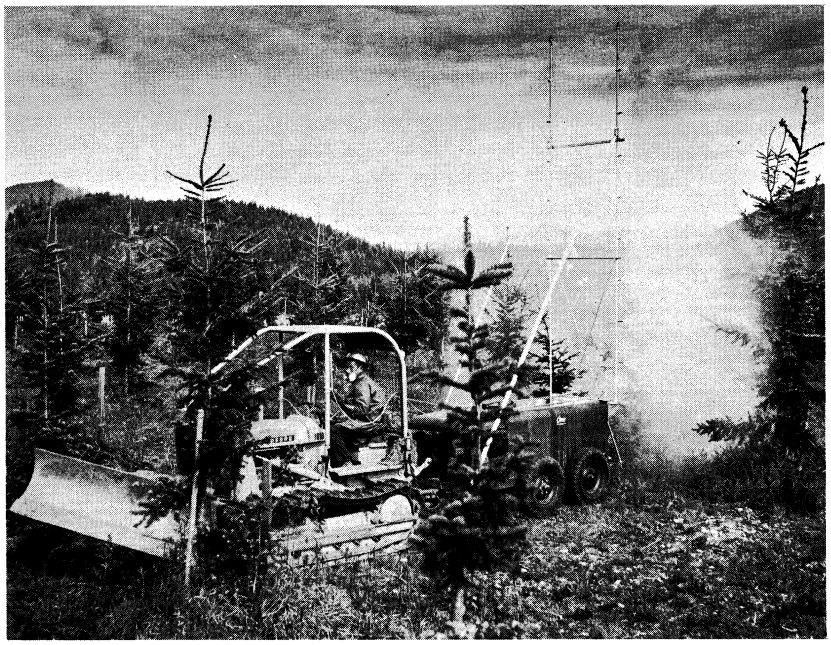
The detection and evaluation of cone and seed insects have become important with the establishment of Douglas-fir production areas on many of the westside National Forests. Some of the major cone and seed insects causing problems are as follows:

Common Name	
Douglas-fir cone midge	*Contarinia oregonensis* Foote
Scale midge	*Contarinia washingtonensis* Johnson
Douglas-fir cone moth	*Barbara colfaxiana* (Kearf.)
Fir cone worm	*Dioryctria abietella* (D. & S.)
Douglas-fir seed chalcid	*Megastigmus spermatrophus* Wachtl

The 1966 Douglas-fir cone crop was generally very good and the seeds were viable. The seed and cone insects were attracted but scattered and absorbed by the plentiful crop and their damage was considered to be light. In contrast the 1967 crop was very light and the lack of pollen reduced filled seed numbers. Cones at the Siskiyou and Olympic National Forests seed areas were heavily infested with cone midges. Cone moths continue to reduce seed yield at the Peavine seed production area on the Rogue River National Forest. The lack of filled seed reduced Douglas-fir seed chalcid impact. Remaining seed production areas contained so few cones that it would be too costly to collect and evaluate the insect problems.

A limited cone and seed insect control project was carried on at Buckhead seed production area an the Willamette National Forest. A one percent dimethoate spray was applied by ground hydraulic equipment. Total seed loss of the unsprayed cones amounted to 60 percent while the sprayed cones sustained an 8 percent loss.

Early indications reveal that the Douglas-fir cone crop in 1968 might be heavy. Pollen production in some areas is also expected to be heavy.



Spraying to control Douglas-fir cone and seed insects in a seed orchard.

OTHER FOREST PEST PROBLEMS

A TENT CATERPILLAR, *Malacosoma* sp.

Larval feeding caused moderate to heavy defoliation on red alder in the Coast Range of Oregon from the Columbia River south to the Coquille River (table 32). Some defoliation is expected in 1968. Control is not needed since parasites usually check most outbreaks before any tree killing occurs.

HEMLOCK SAWFLY, *Neodiprion tsugae* Midd

Very light defoliation of western hemlock occurred on the Bear Springs District, Mt. Hood National Forest, Oregon, and around Spirit Lake on the Gifford Pinchot National Forest, Washington. The trend is undetermined, but is presumed to be downward. No control is needed in 1968. High parasitism should hold tree damage to a low level.

SAWFLIES, *Neodiprion* spp.

Moderate but limited damage occurred in true fir stands on the Winema and Mt. Hood National Forest in Oregon (table 33). A different *Neodiprion* sawfly was found defoliating knobcone pine on the Siskiyou National Forests (table 34). The trend is unknown for either of the two species. Control is seldom necessary as parasites usually check most sawfly outbreaks in a year or two.

BLACK-HEADED BUDWORM, *Acleris variana* (Fern.)

In several true fir and Douglas-fir stands, very light populations exist on the Mt. Hood National Forest in Oregon and on the Gifford Pinchot National Forest in Washington. Elsewhere, this insect was more prevalent than normal, but it caused no damage. No large outbreaks are expected in 1968.

DOUGLAS-FIR TUSSOCK MOTH, *Hemerocampa pseudotsugata* McD.

Douglas-fir tussock moth was not found at any of the 30 permanent ground plots in Oregon and Washington. These plots were established in 1966 and have been visited annually to detect very light tussock moth and other defoliator populations.

SPRUCE BUDWORM, *Choristoneura fumiferana* (Clem.)

Spruce budworm was not detected in either Oregon or Washington. The same 60 plots used for the Douglas-fir tussock moth ground surveys are used for the spruce budworm.

SPRUCE APHID, *Neomyzaphis abietina* (Wlkr.)

Spruce aphid caused light defoliation to Sitka spruce along the Columbia River in Oregon and Washington. The trend is unknown. Control is not needed in 1968.

GREEN-STRIPED FOREST LOOPER, *Melanophia imitata* (Wlkr.)

The green-striped forest looper was found on several of the hemlock looper plots in Oregon and Washington, but no serious defoliation is expected in 1968.

CYPRESS TIP MOTH, *Argyresthia* prob. *franciscella* Busck

A Cypress tip moth caused light to moderate defoliation of western redcedar in the Ozette Lake area of the Olympic National Park, Washington. Severe tree damage has not occurred, nor is any expected. Moth populations should lower next year due to high larval parasitism.

1/ N.F., National Forest

ALDER FLEA BEETLE, *Altica ambiens* (LeC.)

Light larval feeding was observed on red alder in the Coast Range in Oregon. Continued defoliation is expected in localized areas in 1968. Control is seldom necessary since most outbreaks subside before tree mortality occurs.

DOUGLAS-FIR ENGRAVER, *Scolytus unispinosus* (LeC.)

Several epidemics of the Douglas-fir engraver were detected in Oregon on the Siuslaw and Umpqua National Forests (table 35). The damage occurs in the tops of Douglas-firs. The trend is expected to remain static next year. Small drought-weakened trees in plantations were killed by the beetle on the Willamette National Forest. Control efforts against this pest are limited to salvaging accessible, merchantable, infested trees and those of declining thrift in the outbreak centers.

DYING HEMLOCK

The acreage of mature and overmature western hemlock dying from unknown causes decreased slightly (table 36). The majority of the dying hemlock was found on the Mt. Baker and Olympic National Forests and the Olympic National Park (table 37). Two small centers of dying hemlock were found on the Gifford Pinchot National Forest.

TREE DAMAGE BY BEARS

Tree damage and killing by bears in young Douglas-fir and western hemlock stands increased in Washington and decreased in Oregon (table 38). The seriousness of this problem is compounded by bears habitually working in understocked stands. Serious damage occurred on the Siuslaw and Willamette National Forests and on the Northwest Oregon District (table 39). In Washington the most seriously damaged areas were on the Gifford Pinchot, Olympic, and Snoqualmie National Forests and the Southwest Washington District. The outlook for next year is for little overall change with local areas increasing or decreasing in damage received.

APPENDIX

Aerial surveys: The general aerial detection surveys were made in July and August. The surveys were coordinated by the U. S. Forest Service in cooperation with the Oregon State Department of Forestry and the Washington State Department of Natural Resources. Larch casebearer surveys in early June in northeastern Washington were coordinated with Region 1, U. S. Forest Service, Missoula Montana. Flying time for all aerial surveys totaled 222.8 hours (table 40).
